Fan (Chunju et al., 2007) proposed a fault location method employing wavelet fuzzy neural network to use post-fault transient and steady-state measurements. However, this method was not influenced by the fault resistance and load current but he assumed the system was balanced and it tacked a lot of time in off line mode the training and calculation for the fault location in industrial distribution lines.

The proposed travelling wave fault location method is fast and gives accurate fault location and can reduce the power loss. A single terminal fault location method using the time domain and frequency domain characteristics of the fault was proposed in for transmission lines. The method calculates fault distance based on the determined time and velocity.

The fault diagnosis methods based on graph theory mainly include signed directed graph (SDG) and a fault tree method. SDG is a widely used graphical model to describe causality. Fault tree is a special kind of logic diagram. The diagnosis method based on a fault tree is a process of analysis from result to cause.

Contemporary methods for fault location on overhead and underground lines can be classified in two main types: - Methods based on the measurement of post fault line impedance called phasor-based algorithms that use only the fundamental components of the signals. - Methods based on the measurement of the fault generated travelling waves

However, fault location using intelligent methods are challenging since they require training data for processing and are time consuming. In this paper, most of the techniques that have been developed since the past and commonly used to locate and detect faults in distribution systems with distributed generation are reviewed.

This paper presents a comparative study between two fault location methods in distribution network with Distributed Generation (DG). Both methods are based on computing the impedance using fundamental voltage and current signals. The first method uses one-end information and the second uses both ends.

Fault detection, isolation, and recovery is a subfield of control engineering which concerns itself with monitoring a system, identifying when a fault has occurred, and pinpointing the type of fault and its location. Two approaches can be distinguished: A direct pattern recognition of sensor readings that indicate a fault and an analysis of the discrepancy between the sensor readings and expected values, derived from some model. In the latter case, it is typical that a fault is said to be detect

One-ended impedance methods of fault location are a standard feature in most numerical relays. One-ended impedance methods use a simple algorithm, and communication channels and remote data are not required (except when a channel is required to bring the fault location estimate to an
