Drugs interfere with the way neurons send, receive, and process signals via neurotransmitters. Some drugs, such as marijuana and heroin, can activate neurons because their chemical structure mimics that of a natural neurotransmitter in the body. This allows the drugs to attach onto and activate the neurons.

Conditioned taste aversion is arguably the most important learning process that humans and animals possess because it prevents the repeated self-administration of toxic food. It has not only profoundly influenced the content and direction of learning theory, but also has important human nutritional and clinical significance. In addition to its direct relevance to food selection, dietary habits, and eating disorders, it is significant for certain clinical populations that develop it as a consequence of their treatment. The study of conditioned taste aversions has invigorated new theory and research on drug conditioning and addictions, as well as on conditioned immunity. There has also been a substantial amount of recent research exploring the neural substrates of conditioned taste aversion--its neuroanatomy, pharmacology, and role in the molecular and cellular basis of plasticity. This book provides a definitive perspective on the current state of research, theory, and clinical applications for conditioned taste aversion effects and methodology. In each chapter, a leading scholar in the field presents a broad range of studies, along with current findings on the topic, highlighting both the major theoretical landmarks and the significant new perspectives. It will be an important resource for both professional and student researchers, who study conditioning, learning, plasticity, eating disorders, and dietary and ingestive behaviors in neuroscience, cognitive neuroscience, cognitive psychology, developmental psychology, clinical psychology, psychopharmacology, and medicine.

While this book is intended to be an introduction to the neuroanatomy of the limbic system

and to studies of the behavior of animals in which the limbic system is stimulated or damaged, it is primarily intended for advanced students of brain-behavior relationships. I have assumed the reader to have some understanding of the structure of the brain, of basic neurophysiology, and of modern behavioral techniques. It has been written for students in graduate programs in psychobiology, physiological psychology, and the neurosciences, but it also should be of interest to some medical students and to others with catholic interests in the biology of behavior. In the first chapter, I review the structure of the limbic system and in subsequent chapters consider the behavioral effects of lesions and stimulation of components of the limbic system. Supplement information derived from recording the electrical signals of the brain is included where it seems appropriate. The final chapter presents a perspective of the limbic system related to brain stem mechanisms and the neocortex. Understanding the behavioral contributions of the limbic system presupposes understanding how the limbic system interacts with other systems of the brain. v Preface vi Even though there is only one chapter overtly devoted to theoretical issues. various biases of mine influence all chapters. Anyone reading the book with a critical attitude will soon be aware of them. I would like to alert the reader to some of them ahead of time.
